HOW IT WORKS
UPRIGHT, 1981 STYLE

What happens when you drop in a coin?

The quarter rolls through a mech that checks it, then falls past a thin switch wire into the cash box. That one pulse counts the coin, latches the power on, warms the picture tube, tests the board and starts attract mode.

LINE RATE

01 **Coin door and slot**
The quarter goes in here; a reject comes back out of the return.

02 **Coin mech**
Checks the coin's size and metal before letting it through.

03 **Coin switch**
A thin wire the falling coin brushes: one pulse per coin.

04 **Coin chute**
A 30° slope that carries the coin past the switch.

05 **Cash box**
An open box 27 cm below the chute that catches every coin.

06 **Coin meter**
Counts each coin, pulsed by the switch.

07 **Relay, transformer and supply**
The first coin latches the relay and wakes the cabinet.

08 **Game board**
CPU, RAM and ROMs: it tests itself, then runs the game.

09 **Harness and edge connector**
Carries the coin line, the controls and the video to the board.

10 **Monitor, CRT and chassis**
On its side for a vertical game; it warms up in about 2 s.

11 **Marquee lamp**
A fluorescent tube that strikes at power-on.

12 **Control panel**
The stick closes a microswitch underneath; the buttons fire and start.
